COVERAGE IS NOT A HELD-OUT FAMILY TEST

flawed original: what it measured

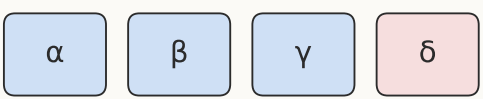
the surface test is INSIDE the training family set
→ 1.000 is coverage, not a new-family result (42-record pool)

high-diversity training sees all families (illustrative)

So the flawed run's 1.000 is COVERAGE of surfaces it trained on,
not generalization to a family it never saw.

---

flawed original vs corrected measured (n=100)



train on α/β/γ, hold out δ

test on family δ
(never seen)

flawed original: test drawn
from training families
→ 1.000 = coverage

corrected: h01/h02 excluded from both arms, n = 100

→ 0.000 (low) vs 0.550 (high) mean

only the corrected run tests an EXCLUDED family
